(54) Title: LOCATION-BASED WEATHER NOWCAST SYSTEM AND METHOD

(57) Abstract: A method for providing location-based nowcast, comprises the steps of: a) initiation of a request, by an end-user, for a time evolution of user-selected nowcast weather parameters, the transmission of the request being made over a public communication network to a nowcast request processor; b) the determination of the end-user's actual location by the nowcast request processor; c) the nowcast request processor gathering raw weather data from data sources; d) processing the raw data into a time-series of nowcast parameter maps; e) extracting the time evolution of the user requested nowcast parameters from the time-series of nowcast parameter maps by positioning the end-user's location on said time series; and f) distributing the requested information to end-user regarding the user-selected nowcast parameters within the extracted time evolution.

# LOCATION-BASED WEATHER NOWCAST SYSTEM AND METHOD

## FIELD OF THE INVENTION

The present invention relates to a system and method for providing individuals with the ability to access information about prevailing weather conditions, on demand. More particularly, the present system and method permit users to request and receive an accurate, immediate, location-based, localized and customized meteorological report which is valid for a short time period. Such weather reporting will be referred to hereinafter as "nowcasting".

## BACKGROUND OF THE INVENTION

The weather is a matter that concerns almost all individuals on practically a daily basis. We use weather information for [i] planning what to wear, [ii] how to travel to work, [iii] whether to proceed with planned activities indoors or outdoors, [iv] whether to engage in outside recreational activities, and [v] whether to expect and prepare for days of particularly severe allergen, smog or ultraviolet exposure.

However, the present methods for obtaining information that could aid with making these plans has, until now, been subject to various constraints, which severely limits the usefulness of the preparation. Most broadcast and Internet-available weather reports provide fairly generalized guidance relating to the weather. In particular, the type of information available is usually related to large periods of time, meteorologically speaking, i.e. time periods can range from as short as 6 hours to as long as 5-7 days. Additionally, the geographical constraints of the reporting are usually confined to large areas, ranging from 25 km<sup>2</sup> to as much as continental distances, common for satellite and radar-image-based reporting on national and international broadcast programming. Even for weather forecasting provided by "local" broadcasts, the geography of any given report is usually based on areas of 5 km radius (about 78 km<sup>2</sup>), and it is not known at resolutions of areas less than 5 km, 3 km or even 1 km in radius.

Another deficiency of known systems for providing weather information is that the systems usually and necessarily address only a limited number of atmospheric conditions, i.e. precipitation, average temperature or temperature range, very general statements regarding cloudiness and wind conditions (sunny, partly cloudy, overcast, cloudy, stormy, light winds with gusting, high winds, etc.) and always with respect to large geographical areas, not necessarily of concern to the individual listener or viewer. One only hears about smog, ultraviolet or pollen conditions in extreme circumstances. Despite the existence of data gathering systems for many atmospheric conditions and at relatively high resolutions or degrees of localization, there is no known system or method for making the power of such data gathering and processing systems available to the general public. Nor has there been a method or system for permitting the general public to extract specifically desired information.

Known systems for on-demand weather forecasting provided by Websites such as the Weather Channel website or the UK's Met Office Website are available for obtaining limited weather-related information based on relatively low-resolution geographical limitations such as zip (postal) code by clicking on a map. However, these systems are similarly limited in the frequency of the updates of the underlying weather information database from which the user receives the answer to his query. Additionally, the type of information available is essentially completely determined by the information provider and does not in any way relate to the specific real-time needs of the user. Moreover, while the information purports to be postal-code localized, it is in fact often simply drawn from a weather map having information regarding a much larger area, i.e. at a fairly low resolution, and which is refreshed once every hour or less frequently. Such weather forecast is extremely probabilistic, due to the extended periods of time which are sought to be covered (e.g. six hours or more).

People today are more time-constrained than ever before and their leisure time is increasingly fragmented and subject to the mercy of the weather. In general, people need help to make the most from the limited time they have and to improve the quality of their decision-making. In fact, the effects of the weather impacts many aspects of human endeavors.

Thus, there is a demonstrated need for a system that is capable of providing weather information for highly localized areas. Furthermore, there is a need for a system which provides answers to highly individualized weather-related queries.

Additionally, the information provided by such a system should offer accurate guidance, i.e. over a short time period (less than one hour).

The system should be able to answer individual needs and demands, and offer information that is both accurate and easily and cheaply accessible.

The information offered should cover all various angles of interest - a person suffering from asthma or allergies could find out, for example, the fog status in London or the pollen count in Teaneck, New Jersey with the same kind of ease and convenience as finding out rain predictions for the following weekend.

#### **OBJECTS AND SUMMARY OF THE INVENTION**

Therefore it is an object of the present invention to provide a user with easy access to individualized information regarding meteorological conditions.

It is a further object of the present invention to provide a user with a user-friendly means for obtaining highly localized meteorological condition reporting.

It is a further objective of the present invention to enable a mobile user to get real-time information about the environmental and meteorological changes that are expected with a high level of certainty to occur in the immediate future.

It is a further objective of the present invention to enable a user to get personal environmental and meteorological data for different specified geographical locations based on a preselectable personal profile.

It is yet a further object of the present invention to create a direct weather-interactive relationship between point-of-sale marketing and the immediate weather, for example emphasizing an on-sale item according to real-time weather conditions. For

example, offering "new umbrellas at \$9.99" in the face of an eminent rapid-onset rain storm.

Yet a further object of the present invention can be integration into a "smart" house that can be proactive in advance of real-time weather changes, for example: closing the windows when heavy rain / dust storm is expected, adjusting an air-conditioning system to a real-time change in pollution levels or local sunshine levels, etc.

Still a further object of the present invention is to provide integration of public transportation arrival/departure information with local, immediate nowcast information, thereby enabling commuters to decide, for example, whether to wait in pleasant weather for a delayed train or to start looking for a more immediate transportation alternatives in view of an oncoming or merely apparent thunder storm.

Yet a further object of the present invention can permit the creation of individualized weather alerts to notify an individual of the occurrence or impending occurrence of a specific weather condition. For example, a mother can request notification, by e-mail, SMS text, paging or cell phone call-back or any wireless data related warning such as animated icon with sound on GPRS network, if the weather in the park where her children are playing is presently or about to become adverse.

These objectives and others not mentioned hereinabove are accomplished by the system and method of the present invention in which an end-user uses a simple, user-friendly interface on an Internet browser, WAP, GPRS or any other data/voice network interface to either activate a saved nowcast profile (saved locally or on a nowcast provider's server), or to construct and execute a new query to obtain selectable meteorological information. The interface and/or query are transmitted over a public communication network, such as the Internet or a cellular phone network (or by any other means) to a nowcast-provider's system. Once the end-user selects the parameters of the data she wants, i.e. the type of meteorological condition that interests her, the location of interest, and the time frame and time intervals of interest (up to one hour, as frequent as one-minute intervals based on data-refresh intervals as often as once every 5 minutes), the software of the present invention builds and initiates a request for the development and delivery of a time

evolution for the end-user-selected nowcast parameters based either on the actual location of the end-user as determined for example by cellular locating technology, GPS location, or end-user input (especially if the end-user is interested in a location remote from her immediate network connection vicinity).

The nowcast-provider's server communicates with servers at meteorological centers (private or governmental), downloads and Processes raw meteorological data such as satellite and radar maps using special meteorological methods and algorithms to provide a nowcasting map of the location of interest, comprising a series of time slice intervals as small as 1km<sup>2</sup> in area for a variety of meteorological and environmental information for time periods of from 1 minute to 60 minutes. The maps are translated to user-friendly tables and a reply is generated and returned to the end-user.

Different maps may be generated according to their end-user demands. Exemplary embodiments of uses include when a extreme sports tour company asks to receive accurate data that concerns them and their clients with real-time information of severe weather heading towards their location. Nursing home personnel may be interested in local smog density mapping as that may affect residents that remain outdoors or that are on field trips. Teacher's may want UV radiation mapping to be warned of changes in potential sun exposure due to changing local cloud conditions, etc.

In an exemplary embodiment of the present invention, end-users can create an alert enquiry whereby the nowcast-provider updates the mapping for particular parameters and creates an alert which is sent to the end-user upon the occurrence of the user-defined trigger.

In another exemplary embodiment, a smart house or other intelligent structure can be programmed to respond to now-cast alerts by preparing or adjusting the home's environmental control settings for the current climactic conditions. For example, a house connected to the Internet that also has automated environmental controls can close it's windows and activate air filters when alerted that a smog condition or brush fire smoke condition is approaching. The same house can close windows before a rainstorm starts, and reopen them when the rain has passed. The house can lower

shades before the sun starts to shine intensely. A home in a region where outside temperatures are shifting dramatically can anticipate the shifting outside temperature fluctuations with more energy-conserving measures like opening or closing windows, as appropriate, rather than remaining closed all day and relying solely on an air-conditioning system's thermostat. Similarly, a smart house can be informed of impending strong wind conditions and store, move or otherwise protect outside fixtures, such as a satellite dish.

In another exemplary embodiment of the present invention, communications companies can use the information from nowcasting to anticipate and prevent weather-related service outages, for example, when a satellite television company receives an alert of severe incoming weather at a particular download station, it can temporarily reroute the traffic to and from that station to a station outside the impact zone until the severe weather condition subsides and or alert its end users of possible difficulties in receptions and when the broadcast is expected to return to normal quality.

### **BRIEF DESCRIPTION OF THE DRAWINGS**

The following detailed description of exemplary embodiments of the present invention can best be understood by reference to the accompanying drawings, in which:

Fig. 1 is a block diagram representing a location-based nowcasting system according to an exemplary embodiment of the present invention;

FIG. 2 depicts two zone maps and a personal nowcasting matrix according to an exemplary embodiment of the present invention;

Fig. 3 is a flowchart illustrating an example of some of the possible components of an end-user's personal nowcasting profile in accordance with an exemplary embodiment of the present invention;

Fig.4 illustrates an exemplary embodiment of a flow chart describing an algorithm in accordance with one exemplary embodiment of the present invention;

Figs. 5a-e illustrate components of an example of the input fields for establishing or modifying an end-user's personal nowcast profile and alerts; and

Fig. 6 illustrates application of an exemplary embodiment of the present invention to an intelligent building structure.

## **DETAILED DESCRIPTION OF THE INVENTION**

With reference to Fig. 1, an exemplary embodiment of a location-based nowcasting system **10** according to the present invention comprises a processing unit **18** and a meteorological database **20** located at a nowcast request processor **30**. Nowcast request processor **30** can be a server and can be located at or in communication with meteorological centers or as privately owned or operated centers by private companies, such as cellular communications, news and weather information providers and the like.

End-users **36** use various means of communication, such as Internet enabled-PCs, wireless PDAs, cellular phones, alphanumeric pagers, and the like to be connected with a WAN such as the Internet, or a cellular communications network, via local clients **22**, **24** and **26**, with examples here shown as wireless content providers, WAP service providers, Internet service providers (ISPs) and third-party content and data providers, respectively. Local clients **22**, **24** and **26** could each have incorporated therein a nowcast request processor **30**, or they could be communicatively connected to a remote nowcast request processor **30**.

A nowcast request is initiated by an end-user **36**, or may be programmed to auto-initiate, and is transmitted to the nowcast request processor **30**, via its appropriate local client **22**, **24**, or **26**, which transmits the request to a nowcast request processor **30**. Methods for user creation and initiation of the request will be described in further detail herein below with reference to Figs. 6a-e

In one exemplary embodiment, the processing unit 18 receives a request and first determines if the request relates to a geographical region which is "covered" by the particular nowcast request processor 30 or if the region about which the request is concerned is covered by a different nowcast request processor 30. If the latter, the request is forwarded to the appropriate nowcast request processor 30 and if the former, a processing stage is entered. In another exemplary embodiment, the determination of which nowcast request processor 30 should process the request can be made by the local client 34. The processing unit 18 is in a constant state of requesting, receiving and analyzing a variety of data such as Doppler and radar images 12 and satellite images 14 wind direction and speed measurements, supplied by local or external meteorological services 16 or by private sources 32, in addition to data from environmental air sampling stations for pollen, smog, and pollutants, and topographical data.

## EXAMPLES OF DATA SOURCES AND DATA DERIVED THEREFROM

### 1. Weather satellites

Data source: Met-Service or Nooly's own reception station.

Satellite type: METEOSAT Second Generation (for Israel and the European coverage). GOES for the western hemisphere.

Data frequency: Every 15 minutes.

Satellite parameters: Radiation at 12 wavelengths in the visible and infra-red.

Satellite data resolution: 4 km.

Retrieved meteorological parameters:

- Surface temperature
- Cloud properties:
  - Existence
  - Height
  - Thickness
  - Type: rain bearing or nice weather cloud
  - Movement
  - Development trend
- Dust storms or large scale air pollution

### 2. Weather radars

Data source: Met-Service.

Radar type: Doppler radar transmitting at a wavelength of 5 or 10 cm.

Data frequency: Every 1 to 5 minutes. Data resolution: 1 km radially by 1 degree azimuthally.

Radar parameters:

- Precipitation reflectivity
- Radial velocity

Retrieved meteorological parameters:

- Precipitation existence and type: rain, hail, snow
- Precipitation intensity: light, moderate, heavy
- Precipitation Movement
- Precipitation Development trend
- Winds

### 3. Automatic weather stations

Data source: Met-Service.

Data frequency: Every 10 minutes

Reported parameters:

- Wind direction and velocity
- Temperature
- Humidity
- Solar radiation
- UV radiation
- Rain intensity
- Barometric pressure

### 4. Air pollution monitoring stations

Data source: EPA, Municipalities, power generation utilities, etc.

Data frequency: Every 10 minutes to 1 hour.

Reported parameters:

- Pollutant gases: Ozone, SO<sub>2</sub>, Nox, CO
- Pollutant particles: PM10, PM2.5

5. Short range forecasts standard meteorological gridded data:

Data source: Met-Service.

Forecast range: The forecast is based on data collected 6 to 12 hours before present. The forecast range can be for anywhere from 0 to 5 days.

Forecast methodology: The forecast is computed by weather models that calculate the meteorological parameters at grid resolution of several tens of km. The forecasted fields are for air pressure, temperature, humidity, winds, clouds and precipitation.

Forecast accuracy: The shorter the time into the future about which one is producing a forecast, the greater will be the accuracy of the forecast. The best accuracy therefore is for the immediate future. However, even an "immediate future" that is based on data collected 6 to 12 hours before the present (because the collection and calculation times take that long) will have accuracy that is already degraded to the extent that it cannot resolve events (e.g., start and stop of rain) and provide only probabilistic forecast, at geographical accuracy of many tens of km.

6. Geographical information:

- Topographical maps
- Pollution sources and their dependence on time of the day and day of the week.
- Geographical latitude, longitude, and the time of the day, as they determine the position of the sun and its energy output reaching the atmosphere and the surface.
- Sea surface temperature.

As mentioned hereinabove, the above data sources, at a level of detail necessary for producing a truly accurate nowcast, are not available for the general public, and even if they were, the analysis of the data to the accuracy required to produce an individualized nowcast in a few minutes (or less) is beyond human skills without the aid of the algorithms for data-gathering and processing which are described herein.

The processing unit 18 uses algorithms for analyzing meteorological data (as will be described further herein below with reference to Figs. 3 and 4). In the processing stage, the processing unit 18 extracts the specific time slice maps relevant to answering the request and prepares a weather nowcast, in layman's terms, to be sent back to the end-user in response, relating to a tightly focused target area for up to a 60 minute total time period in increments as small as 1 minute apart.

After the processing stage, the nowcasts are sent from the nowcast request processor 30 to the end-user's device (PC, notepad, cel phone, wireless PDA, pager, embedded device, 3<sup>rd</sup> party application etc), via the appropriate local clients 22,24,26. It should be understood that the nowcast request processor can be physically located in the same place as the local client 34.

A 3<sup>rd</sup> party application user can be a private, or a governmental company giving its clients essential nowcasting information. For example a 3<sup>rd</sup> party application can be placed at local branches of a national supermarket chain. In those branches where heavy rain is about to begin falling, large screens can anticipate the weather change by recommending that customers buy an umbrella due to the heavy rain that will start falling in about 10 minutes for an hour, or be prepared to have a cup of hot chocolate at the store's café to wait out the rain, rather than go wandering aimlessly in the downpour. In branches where the temperature is about to spike upwards to 35°C for the next 40 minutes, customers at the checkout counter can be advised to buy a cold drink and a hat to beat the coming heat.

In one exemplary embodiment, each local client 34 can choose from a large variety of meteorological data that sort and level of data which it wishes to make available to its end-users 36. Local clients 34 receive personal requests from end-users 36, and provide a personalized nowcasting service to each end-user 36 based on the end-user location and personal profile (as will be described below in reference to Figs. 5a-e).

For example traffic web sites, or cellular companies that give information about traffic jams, can use the nowcast system to recommend to the end local client 34 the best and driest way to their home, work or any place they want to get to. For

safety, end users 34 may receive nowcast data from the nowcast request processor 30 with information regarding foggy and freezing roads in their path. The local clients 34 receive detailed maps of a wanted zones with information about the exact places it will rain, or stop raining in the next 10,20, 30...60 minutes and other meteorological and environment information (as will be described below in reference to Fig. 2) and transmit the nowcasting data to their end-users 36. In a further exemplary embodiment, a cellular local client 22, can even use cellular locating technology to pinpoint the end-user's location and direction of travel or profiled destination to automatically provide specific meteorological information to the end-user about his path home or to work. In cars equipped with trip computers, the information regarding weather-related road conditions could even be fed to the driver via the computer or even used to automatically adjust the vehicle for dealing with the upcoming weather (for example automatically shifting from 2-wheel drive to 4-wheel drive, or turning on fog lights).

With reference to FIG. 2, an example of the process 80 of building a time slice matrix 90 incorporates taking data from radar maps 82 and satellite imagery maps 84 as well as topographical maps and whatever other data maps are relevant to the request (UV, smog, pollen) to build a master map by overlaying the maps. The master map 86 is then compartmentalized and the data from each strip of compartments 87 is then stored in a matrix 90.

In order to supply the end user 36 with personal and exact weather nowcasting data according to his present and future position in the next 10, 20...60 minutes timeslice maps are made which are based on the data in the matrix 90 for the relevant strip of compartments 87.

The general map 86 includes different weather data (parameters) such as temperature, humidity, and wind direction, solar radiation data, and other environmental parameters. The uniqueness and the advantages of the general map 86 are mainly due to the exact weather data the map supplies. This data is achieved by using an algorithms that are highly accurate for stating weather conditions in the immediate future, i.e. a period of less then 60 minutes, and for areas of 5 km radius or less (as will be further explained in Fig. 3).

For example, general map **86** comprises accurate forecasts over a broad geographical region for a given time. General map **86** is divided into a large number of small, defined zone cells **87** as depicted by zone map. From zone map **88**, personal nowcasting matrix **90** is built for each zone cell **87**. Weather data such as pollution, humidity, rainfall, and temperature **92** are placed at the perpendicular side of the table **90**, while a time line 1 to 60 minutes **94** is placed at the horizontal column of the table **90**. Each cell **87** of the zone map **88** has up to 60 columns of data, one row for each kind of data and one column for each minute (although the number 60 could be raised to accommodate the development of more more highly accurate weather algorithms to reflect the user's willingness to accept nowcasts with a larger margin of error, particularly as time wears on).

With reference to FIGs. 3 and 6a-e, a customer service unit **60** shows different nowcast parameters **61** an end-user **36** can activate by transmitting his request (including his personal profile) **100** to a local client **34**. The personal profile may be user-defined by using the input fields shown in Figs. 6a-6e. the parameters **61** are shown here as divided into 4 groups based on the complexity of the underlying algorithms and the difficulty of deriving data therefor. However, it should be understood that further (or fewer) subdivisions may be used in building a nowcasting system and this arrangement has been selected solely to aid in the understanding of the present invention.

The process begins by initializing a nowcast query list containing a user location and personal profile **100**. The user location may be determined based on a handset location using a GPS-based service or cell locating technology enabling the end-user to transmit his exact location in real time. The location could also be at a remote location or defined according to a user's needs in the near future, for example if end-user **36** wants to receive nowcasting information or weather alerts, about weather at the park where his children are playing, he can input the exact location of the park directly into his PC, mobile device, interactive TV and receive back the nowcast of the relevant area. Or end user **36** can input the location where he expects to be about one half-hour hence.

After the query list **100** is appropriately filled by the end-user **36** it is transmitted to the local client **34**, where the request is handled and sent back to the end-user **36**. The end-user **36** receives individualized nowcasting data, based on parameters specified in his personal profile **100** such as, general nowcasting weather parameters **64** (wind, air temperature, surface temperature relative humidity etc.), precipitation **66**, solar radiation **68**, and air pollution **70**.

With respect to a request which includes a query for general nowcasting weather parameters **64**, one of two different processes occurs depending on the end-user request. If the request refers to real-time weather parameters the end user will receive real-time measurements of the weather parameter downloaded from a meteorological service network (where available). However, if the end-user **36** asks for a nowcast for weather parameters 10, 20...60 minutes later, then the requested parameters are extrapolated in time by according to the principles of applying a regional numerical model.

In one exemplary embodiment, end-user **36** derives nowcasting data concerning precipitation **66**, by extracting precipitation intensity from nowcasting maps **86**, **88** (as described in Fig. 2) using a nowcasting algorithm at the time and location requested by the end-user **36**. At the end of the process the end-user receives results of precipitation intensity selected from one of the four intensity categories: 1) no rain; 2) light; 3) moderate; and 4) heavy. The user not only gets information about the rain intensity but also its pattern i.e. will it suddenly become a heavy rain or will it slowly become moderate, etc. and when these changes are expected to occur.

Solar and UV radiation data **68** are derived and transmitted to the end-user **36**, taking into account astronomical configurations, and by subtracting cloud scattering retrieved from satellite maps. Air pollution data **70** is transmitted to the end-user **36** by activating two different processes according to the end-user request (personal profile **100**). If the end-user **36** asks for real-time air pollution data the system will send him at least an average (if not more precise) pollutant concentration data based on a monitoring station within a given radius. If the end-user asks for air pollution data for the next 10, 20...60 minutes, the nowcasting system **10** activates

an extrapolating process using a regression model with input from a regional numerical model.

For further guidance on how to implement the above-described methods for deriving UV and air pollution data, reference may be had to: Atmospheric Environment, Shi, Ji Ping and Harrison, Roy M., Oxford, England, 31(24): 4081-4094, December 1997, Refs., figs., tables; and A 3D regional scale photochemical air quality model application to a 3 day summertime episode over Paris, Jaecker-Voirol, A. et al. , Air pollution IV: monitoring, simulation and control., Caussade, B.; Power, H. and Brebbia, C. A. (eds.), Computational Mechanics Publications, 1996. pp. 175-194, Refs., figs.

Referring now to Fig. 4, the precipitation nowcasting algorithm may be based on combinations of different analytic weather forecast methods combining different meteorological maps (radar maps, satellite maps, topographic maps etc.). The process begins 42 by receiving radar maps 12 for the last 5 minutes from meteorological sources as mentioned in Fig 1.

In step 46 automatic echo tracking is activated after at least 3 radar maps 12 are available 44. Precipitation echo tracking and forecasting is a known procedure for tracking evolution and motion of individual clouds. It is known that young clouds are small with strong intensities, and with the maturing of the clouds they dissipate by spreading over large areas with weak intensities. In order to identify the growth and decay of cloud areas it is needed to track the time histories of the echo cells to determine in what stage of their lifecycle they are in.

The radar tracking examines the following two elements:

- a. Vertical profile of intensity: At the growing stage, the precipitation is still at the upper portion of the cloud, and its top is gaining height. At the decaying stages the top descends, and the intensities are greatest near the surface and decaying aloft.
- b. Horizontal profile: A developing storm has compact structure-growing intensities in time, and sharp horizontal gradient of the intensities. A

decaying rain cloud is spreading out to larger area on expense on its intensities.

To complete the picture from radar tracking, satellite images are used. The satellite images are received from meteorological resources as mentioned hereinabove, and are used to seek areas of growth of new elements that still aren't precipitating. The new growing cloudy areas precede the precipitation by 15 to 30 minutes. The cloud tops have to grow above a certain height for start producing precipitation. That height is determined by comparison the satellite data with the radar, finding out what is the cloud with the warmest top that still develops precipitation.

Three more meteorological analyzing methods, that contribute to completing the nowcasting process are:

- [1] the use of Doppler winds to identify areas of converging winds, which precede the formation of clouds. Such features are the basis of forecasting cloud and precipitation development at the time range of one to three hours;
- [2] use of topographical features 330 for modifying the precipitation forecast. The measures are based on the fact that clouds develop more extensively while ascending on a higher ground, and dissipate while moving downhill;
- [3] use of surface temperature for better prediction of the evolution of clouds. Clouds prefer to develop over warmer surface, feeding on the heat energy. For example, on a hot summer day, clouds would form preferentially on the heat island generated by a city. That heat is mapped already by the other data sources, and be used quantitatively in the forecast.

The above operations can be performed, in a simple form, based on the following algorithm:

1. Take the time series of the radar maps for the last 5 minutes **42**.
2. Identify the linear movement of the weather radar echoes, by cross correlation or other methods.
3. Advance the current radar map according to the movement found in step 2, for 1,2,3,...60 minutes in the future, and by that obtain forecasted radar maps for that time interval.

4. Interpret the radar echoes into the various weather elements over the point of interest **87** (the location selected by the end-user), and obtain the weather in that location as a function of time, in 1-minute increments, for the next one hour. The interpretation takes into account the temperature and humidity near the surface and structure of the radar echoes, according to principles known in radar meteorology.
5. Extract from this forecasted weather record the parameters of interest to the user, and transmit them per request, or initiate the transmission if conditions for an alert were fulfilled.

Methods for automatic echo tracking using cross correlation methods have been known since 70's; for example, see, Dixon, M., and G. Wiener, 1993: TITAN: Thunderstorm Identification, Tracking, Analysis, and Nowcasting, a radar-based methodology. Journal of Atmospheric and Oceanic Technology, Boston, MA, 10(6): 785-797, December 1993; Golding, B. W. (1998): Nimrod: a system for generating automated very short range forecasts. Meteorological Applications, Reading Berkshire, UK, 5(1): 1-16; and Leese, J. A., C. S. Novak, and B.B. Clark (1971): An automatic technique for obtaining cloud motion from geostationary satellite data using cross correlation. J. Appl. Meteorology, 10, 118-132.

For each location **87** a linear movement and a forecast quality index are obtained **48**. The process continues in step 50 with improving the linear extrapolation by incorporating trend analysis, external meteorological data and geographical information for example as follows:

1. Combining our existing radar map data with high frequency multispectral geostationary satellite data (GOES and MSG satellite series, providing scans at least once every 15 minutes), thereby allowing identification of growing cloud elements before precipitation starts, usually an area of great deficiency in radar-based forecasting, i.e. the identification of newly developing rain areas that are not observed at the current time;
2. Identification of the development trends according to 3-dimensional evolution of the radar echo field. For example, new developing showers have small

intensities over small horizontal areas and large vertical extent, with peak intensities aloft. Over time the intensities spread to cover larger horizontal area and lower altitudes. In the dissipation stage small intensities are spread over relatively large area; and

3. Additional geographical factors, such as topographically induced enhancement.

The process 52 ends by storing in the processing unit 18 a nowcasting data map for each minute.

With reference to Fig. 5 a screen shot 100 depicting an exemplary embodiment of a nowcasting graphical user interface (GUI) input screen shows different sections the end-user can fill in order to request nowcasting data on a customized and individualized basis, to indicate personal preferences and to establish parameters for alerts relating to various weather conditions. Section 102 illustrates the different meteorological parameters 104 the end-user 36 can select for receiving warnings and alerts during any time of the day concerning the meteorological parameters he selected. For example a sea surfer can get alerts for good wind and surfing conditions directly to his cel phone. Sections 106 illustrate an end-user personal skin profile according to the end-user 36 requests for a selected time 108. Section 110 illustrate a 3<sup>rd</sup> party location personal profile used to receive meteorological data at a 3<sup>rd</sup> party location selected from list 112, to any kind of device 114 the end user selects. The end-user can select his favorite location from section 116.

With reference to Fig. 6, there is shown an exemplary embodiment of a combination between a "smart" house 152 (or any smart intelligent structure, like a warehouse, greenhouse, office building, factory or any other commerical or industrial improvement) and a nowcast server provider 151. A central automation controller 153 in the smart house 152 is connected to the nowcast provider server 151, via a network and is programmed to respond to nowcast alerts, the response being to prepare or adjust the home's environmental control settings 160 for the current climactic conditions.

What is claimed is:

- 1) A method for providing location-based nowcast, comprising the steps of:
  - g) initiation of a request, by a user, for a time evolution of user selected nowcast parameters, by transmission of said request over a public communication network to a computer;
  - h) determining location of user cell;
  - i) receiving raw data from sources, said raw data containing information of any of the following geophysical parameters;
  - j) processing said raw data to create a time-series of forecasted parameters maps;
  - k) extracting a time evolution of user requested nowcast parameters from said time-series of forecasted parameter maps by positioning said cell on said time series; and
  - l) distributing information to said user about the user-selected nowcast parameter within said time evolution.
- 2) A method according to claim 1, wherein said nowcast parameters comprises type, intensity, development and movement of a precipitation.
- 3) A method according to claim 1, wherein said nowcast parameters further comprises cloud properties such as existence, height, thickness, cloud movement, and development of clouds.
- 4) A method according to claim 1, wherein said nowcast parameters further comprises wind direction, velocity, temperature, humidity, solar radiation, u.v radiation, and barometric pressure.
- 5) A method according to claim 1, wherein said nowcast parameters further comprises pollution data such as: pollutant gases and pollutant particles.
- 6) A method according to claim 1, wherein said nowcast parameters further comprises environmental parameters including: heat stress, wind-chill factor,

frost, safe exposure time for various skin types, safe time for avoiding heat stroke, and air quality health index.

- 7) A method according to claim 1, wherein said raw data is received from data sources selected from at least two of the group consisting of weather satellites, weather radar, air quality monitoring stations, and national meteorological services.
- 8) A method according to claim 1, wherein said geophysical parameters further comprises: weather satellite data, weather radar data, air quality data.
- 9) A method for providing location-based meteorological forecast for a period of less than 60 minutes and areas of less than 1 km in radius.

(54) Title: LOCATION-BASED WEATHER NOWCAST SYSTEM AND METHOD

(57) Abstract: A method for providing location-based nowcast, comprises the steps of: a) initiation of a request, by an end-user, for a time evolution of user-selected nowcast weather parameters, the transmission of the request being made over a public communication network to a nowcast request processor; b) the determination of the end-user's actual location by the nowcast request processor; c) the nowcast request processor gathering raw weather data from data sources; d) processing the raw data into a time-series of nowcast parameter maps; e) extracting the time evolution of the user requested nowcast parameters from the time-series of nowcast parameter maps by positioning the end-user's location on said time series; and f) distributing the requested information to end-user regarding the user-selected nowcast parameters within the extracted time evolution.

# INTERNATIONAL SEARCH REPORT

International application No.  
PCT/IL 01/01167

## Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:  
because they relate to subject matter not required to be searched by this Authority, namely:
  
2. ☒ Claims Nos.: 9  
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:  
see FURTHER INFORMATION sheet PCT/ISA/210
  
3. ☐ Claims Nos.:  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

## Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this International application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
  
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
  
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
  
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.

## FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

Continuation of Box I.2

Claims Nos.: 9

Present claim 9 relates to a method defined by reference to a desirable characteristic or property, namely the possibility of forecasting weather conditions for a period of less than 60 minutes and for an area less than 1 km in radius.

The claim covers all methods having this characteristic or property, whereas the application provides support within the meaning of Article 6 PCT and/or disclosure within the meaning of Article 5 PCT for only a very limited number of such methods. In the present case, the claim so lack supports, and the application so lacks disclosure, that a meaningful search over the whole of the claimed scope is impossible. Independent of the above reasoning, the claim also lacks clarity (Article 6 PCT). An attempt is made to define the method by reference to a result to be achieved. Again, this lack of clarity in the present case is such as to render a meaningful search over the whole of the claimed scope impossible. Consequently, the search has been carried out for those parts of the claims which appear to be clear, supported and disclosed, namely those parts relating to the methods, as specified on page 3-6 of the description.

The applicant's attention is drawn to the fact that claims, or parts of claims, relating to inventions in respect of which no international search report has been established need not be the subject of an international preliminary examination (Rule 66.1(e) PCT). The applicant is advised that the EPO policy when acting as an International Preliminary Examining Authority is normally not to carry out a preliminary examination on matter which has not been searched. This is the case irrespective of whether or not the claims are amended following receipt of the search report or during any Chapter II procedure.
